C++ Tricks

 By [Swift](#), [history](#), 3 years ago, , 

****EDIT: A shorter error function ****

WARNING: Many of these things belong to C++11 so use C++11 in order to test anything here :)

I just write a short version for this article, because it's now in the main page. I recommend you to click on "Read more »" and read more :) Here is a short trick for the short version:

I see lots of programmers write code like this one:

```
pair<int, int> p;
vector<int> v;
// ...
p = make_pair(3, 4);
v.push_back(4); v.push_back(5);
```

while you can just do this:

```
pair<int, int> p;
vector<int> v;
// ...
p = {3, 4};
v = {4, 5};
```

1. Assign value by a pair of {} to a container

I see lots of programmers write code like this one:

```
pair<int, int> p;
// ...
p = make_pair(3, 4);
```

while you can just do this:

```
pair<int, int> p;
// ...
p = {3, 4};
```

even a more complex `pair`

```
pair<int, pair<char, long long>> p;
// ...
p = {3, {'a', 811}};
```

What about `vector`, `deque`, `set` and other containers?

```
vector<int> v;
v = {1, 2, 5, 2};
for (auto i: v)
    cout << i << ' ';
cout << '\n';
// prints "1 2 5 2"
```

```

deque<vector<pair<int, int>>> d;
d = {{3, 4}, {5, 6}}, {{1, 2}, {3, 4}}};
for (auto i: d) {
    for (auto j: i)
        cout << j.first << ' ' << j.second << '\n';
    cout << "-\n";
}
// prints "3 4
//         5 6
//         -
//         1 2
//         3 4
//         -"

```

```

set<int> s;
s = {4, 6, 2, 7, 4};
for (auto i: s)
    cout << i << ' ';
cout << '\n';
// prints "2 4 6 7"

```

```

list<int> l;
l = {5, 6, 9, 1};
for (auto i: l)
    cout << i << ' ';
cout << '\n';
// prints "5 6 9 1"

```

```

array<int, 4> a;
a = {5, 8, 9, 2};
for (auto i: a)
    cout << i << ' ';
cout << '\n';
// prints "5 8 9 2"

```

```

tuple<int, int, char> t;
t = {3, 4, 'f'};
cout << get<2>(t) << '\n';

```

Note that it doesn't work for `stack` and `queue` .

2. Name of argument in macros

You can use '#' sign to get exact name of an argument passed to a macro:

```

#define what_is(x) cerr << #x << " is " << x << endl;
// ...
int a_variable = 376;
what_is(a_variable);
// prints "a_variable is 376"
what_is(a_variable * 2 + 1)
// prints "a_variable * 2 + 1 is 753"

```

3. Get rid of those includes!

Simply use

```
#include <bits/stdc++.h>
```

This library includes many of libraries we do need in contest like `algorithm` , `iostream` , `vector` and many more. Believe me you don't need to include anything else!

4. Hidden function (not really hidden but not used often)

[Detailed →](#)

one)

`__gcd(value1, value2)`

You don't need to code Euclidean Algorithm for a gcd function, from now on we can use. This function returns gcd of two numbers.

e.g. `__gcd(18, 27) = 9`.

two)

`__builtin_ffs(x)`

This function returns 1 + least significant 1-bit of x. If x == 0, returns 0. Here x is `int`, this function with suffix 'l' gets a `long` argument and with suffix 'll' gets a `long long` argument.

e.g. `__builtin_ffs(10) = 2` because 10 is '...10 1 0' in base 2 and first 1-bit from right is at index 1 (0-based) and function returns 1 + index.

three)

`__builtin_clz(x)`

This function returns number of leading 0-bits of x which starts from most significant bit position. x is `unsigned int` and like previous function this function with suffix 'l' gets a `unsigned long` argument and with suffix 'll' gets a `unsigned long long` argument. If x == 0, returns an undefined value.

e.g. `__builtin_clz(16) = 27` because 16 is '... 10000'. Number of bits in a `unsigned int` is 32. so function returns `32 - 5 = 27`.

four)

`__builtin_ctz(x)`

This function returns number of trailing 0-bits of x which starts from least significant bit position. x is `unsigned int` and like previous function this function with suffix 'l' gets a `unsigned long` argument and with suffix 'll' gets a `unsigned long long` argument. If x == 0, returns an undefined value.

e.g. `__builtin_ctz(16) = 4` because 16 is '...1 0000'. Number of trailing 0-bits is 4.

five)

`__builtin_popcount(x)`

This function returns number of 1-bits of x. x is `unsigned int` and like previous function this function with suffix 'l' gets a `unsigned long` argument and with suffix 'll' gets a `unsigned long long` argument. If x == 0, returns an undefined value.

e.g. `__builtin_popcount(14) = 3` because 14 is '... 111 0' and has three 1-bits.

Note: There are other `__builtin` functions too, but they are not as useful as these ones.

Note: Other functions are not unknown to bring them here but if you are interested to work with them, I suggest [this website](#).

5. Variadic Functions and Macros

We can have a variadic function. I want to write a sum function which gets a number of ints, and returns sum of them. Look at the code below:

```
int sum() { return 0; }

template<typename... Args>
int sum(int a, Args... args) { return a + sum(args...); }

int main() { cout << sum(5, 7, 2, 2) + sum(3, 4); /* prints "23" */ }
```

In the code above I used a template. `sum(5, 7, 2, 2)` becomes `5 + sum(7, 2, 2)` then `sum(7, 2, 2)`, itself, becomes `7 + sum(2, 2)` and so on... I also declare another sum function which gets 0 arguments and

returns 0.

I can even define a any-type sum function:

```
int sum() { return 0; }

template<typename T, typename... Args>
T sum(T a, Args... args) { return a + sum(args...); }

int main() { cout << sum(5, 7, 2, 2) + sum(3.14, 4.89); /* prints "24.03" */ }
```

Here, I just changed `int` to `T` and added `typename T` to my template.

In C++14 you can also use `auto sum(T a, Args... args)` in order to get sum of mixed types. (Thanks to [slycelote](#) and [Corei13](#))

We can also use variadic macros:

```
#define a_macro(args...) sum(args...)

int sum() { return 0; }

template<typename T, typename... Args>
auto sum(T a, Args... args) { return a + sum(args...); }

int main() { cout << a_macro(5, 7, 2, 2) + a_macro(3.14, 4.89); /* prints "24.03" */ }
```

Using these 2, we can have a great debugging function: (thanks to [lgorjan94](#)) — Updated!

```
#include <bits/stdc++.h>

using namespace std;

#define error(args...) { string _s = #args; replace(_s.begin(), _s.end(), ' ', ' '); stringstream _ss(_s); istream_iterator<string> _it(_ss); err(_it, args); }

void err(istream_iterator<string> it) {}
template<typename T, typename... Args>
void err(istream_iterator<string> it, T a, Args... args) {
    cerr << *it << " = " << a << endl;
    err(++it, args...);
}

int main() {
    int a = 4, b = 8, c = 9;
    error(a, b, c);
}
```

Output:

```
a = 4
b = 8
c = 9
```

This function helps a lot in debugging.

6. Here is C++0x in CF, why still C++?

Variadic functions also belong to C++11 or C++0x, In this section I want to show you some great features of C++11.

one) Range-based For-loop

Here is a piece of an old code:

```
set<int> s = {8, 2, 3, 1};
for (set<int>::iterator it = s.begin(); it != s.end(); ++it)
```

```

    cout << *it << ' ';
// prints "1 2 3 8"

```

Trust me, that's a lot of code for that, just use this:

```

set<int> s = {8, 2, 3, 1};
for (auto it: s)
    cout << it << ' ';
// prints "1 2 3 8"

```

We can also change the values just change `auto` with `auto &`:

```

vector<int> v = {8, 2, 3, 1};
for (auto &it: v)
    it *= 2;
for (auto it: v)
    cout << it << ' ';
// prints "16 4 6 2"

```

two) The Power of `auto`

You don't need to name the type you want to use, C++11 can infer it for you. If you need to loop over iterators of a `set<pair<int, pair<int, int> > >` from begin to end, you need to type `set<pair<int, pair<int, int> > >::iterator` for me it's so suffering! just use `auto it = s.begin()`

also `x.begin()` and `x.end()` now are accessible using `begin(x)` and `end(x)`.

There are more things. I think I said useful features. Maybe I add somethings else to post. If you know anything useful please share with Codeforces community :)

From [Ximera](#)'s comment:

this code:

```

for(i = 1; i <= n; i++) {
    for(j = 1; j <= m; j++)
        cout << a[i][j] << " ";
    cout << "\n";
}

```

is equivalent to this:

```

for(i = 1; i <= n; i++)
    for(j = 1; j <= m; j++)
        cout << a[i][j] << " \n"[j == m];

```

And here is the reason: `" \n"` is a `char*`, `" \n"[0]` is `' '` and `" \n"[1]` is `'\n'`.

From [technetium28](#)'s comment:

Usage of `tie` and `emplace_back`:

```

#define mt make_tuple
#define eb emplace_back
typedef tuple<int,int,int> State; // operator< defined

int main(){
    int a,b,c;
    tie(a,b,c) = mt(1,2,3); // assign
    tie(a,b) = mt(b,a); // swap(a,b)

    vector<pair<int,int>> v;
    v.eb(a,b); // shorter and faster than pb(mp(a,b))

    // Dijkstra
    priority_queue<State> q;
    q.emplace(0,src,-1);
    while(q.size()){
        int dist, node, prev;

```

```

    tie(dist, ode, prev) = q.top(); q.pop();
    dist = -dist;
    // ~ find next state ~
    q.emplace(-new_dist, new_node, node);
}
}

```

And that's why `emplace_back` faster: `emplace_back` is faster than `push_back` 'cause it just construct value at the end of vector but `push_back` construct it somewhere else and then move it to the vector.

Also in the code above you can see how `tie(args...)` works. You can also use `ignore` keyword in `tie` to ignore a value:

```

tuple<int, int, int, char> t (3, 4, 5, 'g');
int a, b;
tie(b, ignore, a, ignore) = t;
cout << a << ' ' << b << '\n';

```

Output: `5 3`

I use this macro and I love it:

```

#define rep(i, begin, end) for (__typeof(end) i = (begin) - ((begin) > (end)); i != (end) - ((begin) > (end)); i += 1 - 2 * ((begin) > (end)))

```

First of all, you don't need to name the type you want to use. Second of all it goes forwards and backwards based on $(begin > end)$ condition. e.g. `rep(i, 1, 10)` is 1, 2, ..., 8, 9 and `rep(i, 10, 1)` is 9, 8, ..., 2, 1

It works well with different types e.g.

```

vector<int> v = {4, 5, 6, 4, 8};
rep(it, end(v), begin(v))
    cout << *it << ' ';
// prints "8 4 6 5 4"

```

Also there is another great feature of C++11, lambda functions!

Lambdas are like other languages' closure. It defines like this:

```

[capture list](parameters) -> return value { body }

```

one) Capture List: simple! We don't need it here, so just put `[]`

two) parameters: simple! e.g. `int x, string s`

three) return value: simple again! e.g. `pair<int, int>` which can be omitted most of the times (thanks to [Jacob](#))

four) body: contains function bodies, and returns return value.

e.g.

```

auto f = [] (int a, int b) -> int { return a + b; };
cout << f(1, 2); // prints "3"

```

You can use lambdas in `for_each`, `sort` and many more STL functions:

```

vector<int> v = {3, 1, 2, 1, 8};
sort(begin(v), end(v), [] (int a, int b) { return a > b; });
for (auto i: v) cout << i << ' ';

```

Output:

`8 3 2 1 1`

From [Igorjan94](#)'s comment:

Usage of `move` :

```

cout << valid_email << " is valid\n";
else
    cout << valid_email << " is invalid\n";

if (regex_match(invalid_email, email_pattern))
    cout << invalid_email << " is valid\n";
else
    cout << invalid_email << " is invalid\n";

```

Output:

```

swift@codeforces.com is valid
hello world is invalid

```

Note: You can learn Regex in [this website](#).

three) User-defined literals

You already know literals from C++ like: `0xA`, `100011`, `3.14f` and so on...

Now you can have your own custom literals! Sounds great :) So let's see an example:

```

long long operator "" _m(unsigned long long literal) {
    return literal;
}

long double operator "" _cm(unsigned long long literal) {
    return literal / 100.0;
}

long long operator "" _km(unsigned long long literal) {
    return literal * 1000;
}

int main() {
    // See results in meter:
    cout << 250_m << " meters \n"; // Prints 250 meters
    cout << 12_km << " meters \n"; // Prints 12000 meters
    cout << 421_cm << " meters \n"; // Prints 4.21 meters
}

```

Note that a literal should start with an underscore (`_`). We declare a new literal by this pattern:

```
[returnType] operator "" _[name]([parameters]) { [body] }
```

note that parameters only can be one of these:

```
(const char *)
```

```
(unsigned long long int)
```

```
(long double)
```

```
(char)
```

```
(wchar_t)
```

```
(char16_t)
```

```
(char32_t)
```

```
(const char *, size_t)
```

```
(const wchar_t *, size_t)
```

```
(const char16_t *, size_t)
```

```
(const char32_t *, size_t)
```

Literals also can be used with templates.

To be continued :)

It's better to use `auto&` in range-based loop when the object is not primitive (e.g pair, vector). UPD: I realized that you mention it at the end, but there are some code written poorly because of that in the first part.

→ [Reply](#)

2 years ago, # ^ | ☆

▲ 0 ▼

samiemad

actually, compiler optimizations will get rid of the extra copy operations if you are not modifying the element. so I don't think it will be any slower in runtime compared to `auto&`.

You can use `auto&` if you are too suspicious, but I don't think that the first part is categorized as 'written poorly'. it is just OK.

→ [Reply](#)

retrograd

In CF, use `GNU C++0x 4` instead of `GNU C++ 4.7`.

Get latest GCC, and from your terminal/cmd use one of these flags `-std=gnu++11` or `-std=c++11` You can download it for your computer:

▲ 0 ▼

Swift

1. Go to:

`/Applications/Xcode.app/Contents/Developer/Toolchains/XcodeDefault.xctoolchain/usr/include/c++/v1`2. Create a folder named `bits`3. Add a file into that named `stdc++.h`

4. Edit it and include libraries

And it is still possible to write sum (or other) functions for mixed type using `std::common_type`

```
template <typename A, typename B>
auto sum(A a, B b) -> typename common_type<A, B>::type
{
    return static_cast<typename common_type<A,
B>::type>(a) + static_cast<typename common_type<A,
B>::type>(b);
}
```

Corei13

```
template <typename A, typename B, typename... Args>
auto sum(A a, B b, Args... args) -> typename
common_type <A, B, Args...>::type {
    return sum(sum(a, b), args...);
}

int main() {
    cout << sum(5, 7, 2, 2) + sum(3.14, 4.89) << endl;
    // 24.03
    cout << sum (complex <double>(1, 2), 1.3, 2) <<
endl;    // (4.3,2)
}
```

May be you can tell something more about this

```
for(i = 1; i <= n; i++) {
    for(j = 1; j <= m; j++)
        cout << a[i][j] << " ";
    cout << "\n";
}
```

```
for(i = 1; i <= n; i++)
    for(j = 1; j <= m; j++)
        cout << a[i][j] << " \n"[j == m];
```

→ Reply

Ximera

3 years ago, # ^ | ☆

← Rev. 3

▲ +32 ▼

Well, Great creativity :)

`" \n"` is a `char*`, `"\n"[0]` is `'\n'` and `"\n"[1]` is `'\n'`.

Also this is a correct one too:

```
for (int i = 1; i <= n; i++)
    for (int j = 1; j <= m; j++)
        cout << a[i][j] << (j == m) ? "\n" : " ";
```

It's because e.g. `a[8]` and `8[a]` are the same thing both of them are `(a + 8)*` and `(8 + a)*`.

Do you know tie and emplace ?

```
#define mt make_tuple
#define eb emplace_back
typedef tuple<int,int,int> State; // operator< defined
```

```
int main(){
    int a,b,c;
    tie(a,b,c) = mt(1,2,3); // assign
    tie(a,b) = mt(b,a); // swap(a,b)

    vector<pair<int,int>> v;
    // push back
    // push back and faster than push_back(a,b)
```

```

v.erase(v.begin(), v.begin() + 1); // slower and faster than pop(v.begin(), v.begin() + 1)

// Dijkstra
priority_queue<State> q;
q.emplace(0, src, -1);
while(q.size()){
    int dist, node, prev;
    tie(dist, node, prev) = q.top(); q.pop();
    dist = -dist;
    // ~ find next state ~
    q.emplace(-new_dist, new_node, node);
}
}
}
→ Reply

```

3 years ago, # ^ | ☆

▲ 0 ▼

Such a great feature.

Swift

`emplace_back` is faster than `push_back` 'cause it just construct value at the end of vector but `push_back` construct it somewhere else and then move it to the vector.

Can you get the previous element in an, let's say, vector using `auto`? Here is why `auto` is not the best option for dp-like tasks where you need information from the previous elements.

→ Reply

3 years ago, # ^ | ☆

← Rev. 3 ▲ +4 ▼

Use this approach:

```

vector<int> dp = {4, 5, 6, 4, 8};
for (auto i = ++dp.begin(); i != dp.end(); ++i)
    *i += *(i - 1);
for (auto i: dp)
    cout << i << '\n';

```

Swift

Output:

```

4
9
15
19
27

```

Use range-based for-loop only when you want exact element, when you need to access other elements use normal for-loop, but this doesn't mean that you can't use `auto` in that for-loop.

→ Reply

HekpoMaH

3 years ago, # ^ | ☆

▲ 0 ▼

Hm, I didn't know it could be done. Still, it is easier with normal for loop.

→ Reply

3 years ago, # ^ | ☆

← Rev. 3 ▲ +3 ▼

Swift

Btw, using `auto` is just for inferring type you are working with. If your type is `int`, it's better to use that ('cause it's just 3 characters) but if your type is `std::vector<std::pair<std::set<int>, bool>>::iterator` so I think using `auto` is a must :)

In 2, I use:

r1ac

```
#define DB(x) cerr << __LINE__ << ": " << #x << " = " << (x) << endl
```

In this way I get the number of the line in which this instruction is executed. It's useful when we have more than one variable with the same name. Also, x needs to be enclosed in parenthesis due to operators precedence.

if i have a vector < pair<int, pair<int, int> > > a;

could i use emplace_back to insert {1, {2, 3}}? i tries to emplace_back({1, {2, 3}} but of

Tensor

could I use `emplace_back` to insert i, j, k times to `emplace_back(1, 2, 3)`, but of course it's an error.

thanks in advance :-)

→ [Reply](#)

AlexDmitriev

3 years ago, # ^ | ☆

You could `emplace_back(1, mp(2,3))`

→ [Reply](#)

Tensor

3 years ago, # ^ | ☆

thank you for replying. i was looking forward for a method like that above something like $(1, 2, 3)$; as i don't like using macros, something that's faster to write.

thanks in advance :)

→ [Reply](#)

Swift

3 years ago, # ^ | ☆

Don't use `pair<int, pair<int, int>>` ! Code less and use `tuple<int, int, int>` :

```
vector<tuple<int, int, int>> v;
v.emplace_back(1, 2, 3);
```

→ [Reply](#)

Baklazan

3 years ago, # ^ | ☆

Well, actually sometimes `pair<int, pair<int,int> > x;` may make more sense than `tuple<int,int,int> x;`, for instance when `x.second` are coordinates of some point and `x.first` is some property of this point.

→ [Reply](#)

3 years ago, # ^ | ☆

← Rev. 2

+10

When working with tuples, you don't really use `get(tuple)` you do use `tie`:

Swift

```
tie(point_property, pointx, pointy) =
some_tuple;
```

And that makes sense.

→ [Reply](#)

AlexDmitriev

3 years ago, # ^ | ☆

then you probably have that point as a variable, not as two coordinates.

→ [Reply](#)

3 years ago, # ^ | ☆

I often use

Baklazan

```
#define X first
#define Y second
#define pii pair<int, int>
```

```
pii point;
```

→ [Reply](#)

your debugging function doesn't work for `#args` with spaces so, I think it's better to rewrite `split` to more universal

```
vector<string> split(const string& s, char c) {
    vector<string> v;
    stringstream ss(s);
    string x;
    while (getline(ss, x, c))
        v.emplace_back(x);
    return std::move(v);
}
```

Igorjan94

(Note no copying because of `move`, another `cpp` trick) and macro will be:

```
#define err(args...) {\
    vector<string> _v = split(#args, ' '); \
    err(_v.begin(), args); \
}
```

→ Reply

3 years ago, # ^ | ☆ ▲ 0 ▼

It also brings default space before arguments, e.g. `err(a, b)` outputs:

```
a = value1
b = value2
```

Swift

but it's better for arguments like `a + b` so I'll replace it with my code.

→ Reply

3 years ago, # ^ | ☆ ← Rev. 3 ▲ 0 ▼

oh, yep, I forgot I changed your `err` to

```
void err(vector<string>::iterator it) {}
```

Igorjan94

```
void err(vector<string>::iterator it) {}
template<typename T, typename... Args>
void err(vector<string>::iterator it, T a, Args...
args) {
    cerr << it->substr((*it)[0] == ' ') << " = " <<
a << '\n';
    err(++it, args...);
}
→ Reply
```

3 years ago, # ^ | ☆

▲ 0 ▼

if you are interested in it, I also have writeln and readln on variadic templates, which helps to write smth like this:

```
int n; vector<pair<int, pair<int, long long>>> a; long
long l; char c; string s; double d; // just any
combination of fundamental types + vector/pair
readln(n, a, l, c, s, d);
writeln(n, a, l, c, s, d);
```

Igorjan94

you can find it here [9388829](#)(I deleted all spaces for more compact view)
 if trailing space is unimportant, half of code can be deleted:
 it can be simply extended on user's types by overloading ostream and istream operators
 this template is with cin/cout, and this->[9316393](#) with scanf/printf
 yes, looks awful, and for only prewritten use:)
 → Reply

dj3500

3 years ago, # ^ | ☆

One can omit return type in lambda expression in most cases.

P.S. I have to say, 'tie' looks awesome, I need to start using it.

→ Reply

3 years ago, # | ☆

▲ +4 ▼

You haven't to specify return type in lambda functions if all return values are the same type.

```
auto f1 = [](int a, int b) {return a < b;}; // ok: return type is bool
```

```
auto f2 = [](int a, double b) {
    if (a == 0)
        return b;
    else
        return a;}; // error: is return type double or int?
```

```
auto f3 = [](int a, double b)->double {
    if (a == 0)
        return b;
    else
        return a;}; // ok: return type is double
```

```
auto f4 = [](double a, double b) {
    if (a < 0)
        return a;
    else
        return pow(a, b);}; // ok: return type is double
```

see more about lambda functions

→ Reply

3 years ago, # | ☆

▲ +1 ▼

you can even write your own recursive functions inside the main in lambdas that's really

Tensor

you can even write your own recursive functions inside the main in lambdas, that's really cool and useful for less code.

But here instead of using auto you should specify the return type and the parameters type of the lambda expression.

The example which is now given for `move` (define `w = move(v)` and then output contents of `v`) is actually undefined behaviour. What the compiler will actually do in this situation is just swap the contents of the two vectors (`v` with the empty `w`); however, in theory `v` is now "junk" and should not be touched at all (it can not even be a vector with arbitrary contents, but just something referring to some arbitrary place in memory, which might, in theory, no longer correspond to any correct contents of a vector, and it can do basically anything when its methods (such as the range-based for loop) are called).

→ [Reply](#)

I like the string literals functionality. Sometime it can make code much simpler, especially for competitions:

```
#include <iostream>
using namespace std;
```

```
int main() {
    string test = R"END(
        let's test a multiline string
        that can have special chars like ''
        or even ""
        and not to forget \
        and no need to escape!
        This rocks !)END";
    cout << test << endl;
    return 0;
}
```

And the result on ideone can be seen [here](#).

→ [Reply](#)

I didn't know about this! Thank you. Could you please write a tutorial about this, I'll move it to this post.

→ [Reply](#)

3 years ago, # ^ | ☆

▲ +5 ▼

c++11 also introduces a set of [new string literals](#). Some of them are really useful for professional programming, but not very helpful for competitions(like UTF-8, UTF-16 and UTF-32 literals) and thus they are not that much of an interest(you can read about them in the wiki article that I link to). However one type of string literal is particularly interesting — the raw string literal. To write a raw string literal you need to prefix the opening quotes with R and immediately after the quotes you should write some delimiter, the delimiter can be a string of up to 16 characters and should not contain whitespace or control characters. You should terminate the string with the same delimiter before the closing quote and also the string should be in brackets(after the delimiter). Here is an example usage:

```
int main() {
    string test = R"END(
        let's test a multiline string
        that can have special chars like ''
        or even ""
        and not to forget \
        and no need to escape!
        This rocks !
        )END";
    cout << test << endl;
    return 0;
}
```

And the output can be seen [here](#).

Note that the string can span multiple lines and that you don't need to escape special characters in it. In this case I use END as my delimiter.

Following is also useful for GCC. Very fast ASM bit operations:

Note, that **offset** can be ≥ 32 , any valid offset will work. However, I didn't know if inline assembly allowed in CF. Should work.

```

/* Read bit and set to zero */
inline bool btr (volatile void * mem, size_t offset) {
    bool result;
    __asm__ (
        "btr %2, %1; setc %0;"
        : "=r" (result), "+m" (* (volatile long *) mem)
        : "r" (offset)
        : "cc");
    return result;
}

/* Read bit and set to one */
inline bool bts (volatile void * mem, size_t offset) {
    bool result;
    __asm__ (
        "bts %2, %1; setc %0;"
        : "=r" (result), "+m" (* (volatile long *) mem)
        : "r" (offset)
        : "cc");
    return result;
}

/* Bit value */
inline bool bittest (volatile void * mem, size_t offset) {
    bool result;
    __asm__ (
        "bt %1, %2; setc %0;"
        : "=r" (result)
        : "r" (offset), "m" (* (volatile long *) mem)
        : "cc");
    return result;
}

/* Set bit to one */
inline void bitset1 (volatile void * mem, size_t offset) {
    __asm__ ("bts %1, %0;" : "+m" (* (volatile long *) mem) : "r"
(offset) : "cc");
}

/* Set bit to zero */
inline void bitset0 (volatile void * mem, size_t offset) {
    __asm__ ("btr %1, %0;" : "+m" (* (volatile long *) mem) : "r"
(offset) : "cc");
}

```

▲ 0 ▼

Why do you need `volatile` everywhere?

→ [Reply](#)

vsamsonov

3 years ago, # ^ | ☆

← Rev. 2

▲ 0 ▼

Just to make sure that value is actually changed. It gives information to the compiler that memory is changed indirectly (inside **asm** block), to avoid unexpected optimizations. Modern compilers have aggressive optimizations. If you used some value from memory, compiler probably saved it to intermediate register. Let's imagine, that you then called **bitset** on that memory and used value again. Compiler may decide: "Ok, he didn't even touched that **mem** variable, I'll use the old value". But it's wrong. You changed it inside **asm** block. Everything inside **asm** — direct instructions to processor, compiler doesn't know what you are doing there.

→ [Reply](#)

▲ +11 ▼

andreyv

3 years ago, # ^ | ☆

Yes, GCC does not know what is inside the asm block. However, GCC does know which variables are used and modified — you specified this yourself in the asm block input/output operands! In particular, `"m"` should tell GCC that this variable/location in memory is read and modified.

You can see that GCC indeed reloads the value as it should here: <http://goo.gl/Jz8SYH>. If GCC thought the variable was unmodified, it would do

```
movl    $31, %eax
```

instead (comment out the `btr()` call to see this).

Bottom line: `volatile` is not needed in correct code. The only valid uses for `volatile` I can think of are signal handler flags and hardware registers that are mapped in memory.

→ [Reply](#)

3 years ago, # ^ | ☆

▲ 0 ▼

Well, it seems like `volatile` is indeed redundant in this case. Clobber `"m"` should take care of all things. I put it there just in case. Because redundant information isn't a problem, but lack of information is. `volatile` also comes in handy in multithreaded programs, when you are messing up with custom synchronization/locking technique. Actually anything that involves shared memory involves volatile somehow. In regular programs volatile rarely used, because everything is already written (like synchronization primitives/threadsafe data structures...) and program uses high-level functions for this.

→ [Reply](#)

vsamsonov

3 years ago, # ^ | ☆

▲ +8 ▼

I'm sorry for being a nerd, but `volatile` can't be used to implement thread synchronization primitives too. Even `volatile sig_atomic_t` won't do. You are confusing `volatile` with atomic operations, which are two different things.

→ [Reply](#)

andreyv

array<int, 4> a; a = {5, 8, 9, 2};
```

This code fails on `c++11` compilation with error error: no match for 'operator=' in 'a' no known conversion for argument 1 from '' to 'const std::array<int, 4ul>&'

Need additional braces `a = { {5, 8, 9, 2} }`

I wonder then what is the difference between

`__builtin_popcount` and `__builtin_popcountll` as both solution give AC. I thought `__builtin_popcount` should give wrong result if I send long long as an argument.

9506854 --> `__builtin_popcountll`

and 9506856 `__builtin_popcount`

It is not part of c++11(only one of this), but useful cpp functions

```
vector<int> a(n), b(n), c(n);
iota(a.begin(), a.end(), 1); //c++11
// a = 1..10
random_shuffle(a.begin(), a.end());
// a = random permutation of a
partial_sum(a.begin(), a.end(), b.begin());
// b[i] = sum(a[j], j <= i)
adjacent_difference(a.begin(), a.end(), c.begin());
// c[i] = a[i] - (i == 0 ? 0 : a[i - 1])
cout << accumulate(a.begin(), a.end(), 123) << "\n";
// x = 123 + sum(a[i])
cout << inner_product(a.begin(), a.end(), b.begin(), 234) << "\n";
// x = 234 + sum(a[i] * b[i])
```

Igorjan94

All functions have two iterators as input, some of them have output iterators and init values. All operators, used in these functions can be user-defined or standard:

```
cout << accumulate(a.begin(), a.end(), 1, multiplies<int>()) <<
"\n";
// x = product(a[i])
// foldl in functional languages
adjacent_difference(a.begin(), a.end(), c.begin(), [](int a, int
b){return a * b;});
// c[i] = a[i] * (i == 0 ? 1 : a[i - 1])
```

These functions are defined in `<numeric>`

Swift, I think you forgot a semicolon in your perfect tutorial, right here:

```
"""" auto f = [] (int a, int b) -> int { return a + b; } ..HERE.. cout << f(1, 2); // prints "3" """"
```

Using `complex`, `p.real() = x` or `cin >> p.real()` don't work in C++11 but they do in C++98.

→ [Reply](#)

3 years ago, # ^ | ☆

▲ 0 ▼

You can use `p.real(x)` in C++11. I don't know any way to `cin` real

Swift

You can use `print(x)` in C++. I don't know any way to `print` real.

_builtin_wolfy

Here is a trick that might interest you. In C++, a class can inherit from a template instantiation of itself. So you can write `class X: vector<X> {...};` for example. Class X inherits the members of vector and you can use this trick to implement multidimensional arrays, tries, and other useful data structure without using pointers. More [here](#).

C++11 Tricks or Traps?

One should not use this:

```
vector<int> s(5);
for(int i=0;i<5;i++) s[i]=(101*i)%37;
for(int z:s) cout<<s[z]<<' ';
```

instead of this:

```
vector<int> s(5);
for(int i=0;i<5;i++) s[i]=(101*i)%37;
for(int z=0;z<s.size();z++) cout<<s[z]<<' ';
```

or, am I missing something?

→ Reply

3 years ago, # ^ | ☆

← Rev. 2 ▲ +8 ▼

natsukagami

```
for(int z:s) cout<<s[z]<<' ';
```

should be

```
for(int z:s) cout<< z <<' ';
```

There is a tiny typo in the section 6, dijkstra's part: `tie(dist, ode, prev) = q.top(); q.pop();`

should be: `tie(dist, node, prev) = q.top(); q.pop();`

Here's another trick:

For max/min functions, **these functions don't need to take two parameters, they can take more :**)

Instead of writing

instead of writing,

```
int a = 5, b = 6, c = 2, d = 10;
cout << max(a, max(b, max(c, d))) << endl;
```

You can just use "{}" braces around your parameters and insert a list into the max function (works the same for min function) like below:

```
int a = 5, b = 6, c = 2, d = 10;
cout << max( {a,b,c,d} ) << endl;
```

Here's a source code for reference: <http://ideone.com/lllqIK>

→ [Reply](#)

▲ 0 ▼

Hey is there a shortcut to Something like:

```
a = max(a, Something being computed);
```

foundLoveOfMyLife

I always wanted something like: a+=Something being computed for max too. Although a function with variable parameters can be defined in a template but I don't like working with templates! :)

→ [Reply](#)

2 years ago, # ^ | ☆

← Rev. 2 ▲ 0 ▼

What's wrong with templates? This would work just fine:

TimonKnigge

```
template<class T>
maxx(T &l, T r) {
    if (l < r) l = r;
}
```

this crap before.

SarvagyaAgarwal

The link you mentioned isn't working . Can you post it on medium :
→ [Reply](#)

19 months ago, # ^ | ☆

```
#define ftoa(i, x, y, a) for(int i = (x); i != (((x) <
(y)) ? ((y)-(x))/a+1)*a+(x) : (x)-(((x)-(y))/a+1)*a);
i += ((x) < (y)) ? (a) : -(a)
```

I have use this code and try 1000 test cases to make sure that it is correct.

VoMinhThienLong

Here is 3 codes:

By `ftoa`

By normal `for`

[Make test case](#)

Note: to make the test cases you download these 3 codes and then run the third one. It will automatically run.

Why the downvotes I didn't say anything wrong did I ???

Here's a submission by me using what I described (the check function)23252012(I got WA because the idea is wrong not the implementation)

My life now is a lot easier...Thank you [Swift](#).

:)

I'm not sure if this is well known but in C++ you can give a default value to a function for example:

```
void DFS(int node, int par = -1){
```

...

}

```
int main(){
```

```
// input a graph
```

```
DFS(1);
```

```
// rest of the code
```

}

the DFS function works as a normal function but when you don't provide a second parameter it will take the default value you have given it as its value...hope this helps.

:)

Old post, but one important mistake: there should be no `std::move()` call at the end of your `split()` function. `std::move()` should never be used to move automatic objects out of functions.

Also, one more cool thing C++(11?) has is the `throw` instruction and `try/catch`. You can get out of recursive call stacks and treat "No solution" / "Solution found" cases much more easily.

Example:

```
try {
    DFS(0);
    PrintSolution();
} catch (int) {
    PrintNoSolution();
}
```

→ [Reply](#)

retrograd
